

1 Although breast cancer during or after pregnancy is very rare, it is the most common cancer in pregnant women.

It is often diagnosed late due to natural changes in breast tissue.

2

3 Be aware of persistent breast changes and discuss them with your doctor.

Screening tests are known to be safe for both mother and baby. Manual breast examination, ultrasound, mammography or biopsy are safe.

4

5 The best possible treatment for the patient and her baby is considered according to the trimester of pregnancy, the type of cancer and its stage.

Pregnant or not, the prognosis remains the same for a breast cancer patient. There is an increased risk of metastasis in breast cancer diagnosed postpartum.

6

7 Depending on the type of treatment, breastfeeding may remain an option.
